

Ref. 05030016AA

Claims 1-8

Citations 1-6

Remarks:

In Citation 1, technology is disclosed in which, in an EL printer head which arranges lighting elements 2 dimensionally and which is driven by horizontal and vertical scanning circuits, use is made of the printer head width scanning direction, with multiple scanning elements being driven by respectively differing lighting amounts relative to the same spot, a gradation record being established by controlling the number of lighted elements at the time.

In Citation 2, the point is disclosed that, since the EL element lighting output is low, sufficient illumination energy can be applied relative to a photo-sensitive drum by using a printer head formed from 2 dimensionally arranged EL elements, using multiple lighting elements in the width scanning direction of the printer head, and by overlaying the lighting multiple times relative to the same spot.

In Citation 3, the points are disclosed of forming an EL element and its drive circuit on the same insulation substrate, and of constructing the drive circuit at this time from a polycrystalline silicon thin film transistor.

In Citation 4, the point is disclosed of the known technology of using design step modulation in an optical printer.

In Citation 5, with regard to a line printer, the point is disclosed of detecting positional slippage in the primary scanning direction of the recording medium, and to preventing positional slippage by shifting the print data by only the amount corresponding to the positional slippage.

In considering this, the invention relating to Claims 1-8 is nothing more than the appropriate application of the invention disclosed in Citations 1-6.
